Lecture 5:

## Shortest Path Problems

<https://elms.u-aizu.ac.jp>

## Assumption:

- ▶ Let  $G(V, E, W)$  be a weighted graph with **non-negative** edge distances (or costs).
- ▶ For edge  $(u, v)$ , the distance of  $(u, v)$  is denoted by  $d(u, v)$ .
- ▶ The distance of a path  $P$ , denoted by  $d(P)$ , is the sum of the distances of edges in the path.
- ▶ For two nodes  $u$  and  $v$  in  $G$ , the shortest path from  $u$  to  $v$  is the path  $P$  such that  $d(P) = \min\{d(Q) \mid Q \text{ is a path from } u \text{ to } v\}$ .

# Property on shortest path

- ▶ Let  $u \rightarrow v \rightarrow w$  be a shortest path from  $u$  to  $w$ .
- ▶ Then  $u \rightarrow v$  is a shortest path from  $u$  to  $v$  and  $v \rightarrow w$  is a shortest path from  $v$  to  $w$ .

# Shortest path problems

- ▶ Single source shortest path problem and all pairs shortest path problem are most important shortest path problems.
- ▶ Single source shortest path problem is the problem of finding the shortest paths from a specific vertex  $s$ , called **source**, to all other vertices of  $G$  (connected graph).
- ▶ All pairs shortest path problem finds the shortest paths **between every pair** of vertices in  $G$  (sources are all vertices in  $G$ ).

# Single Source Shortest path problem

- ▶ Let  $G(V, E, W)$  be a weighted graph with **non-negative** edge distances, and let  $s$  be a vertex of  $G$  from which every vertex of  $G$  can be reached.
- ▶ Then there exists a spanning tree  $T$  of  $G$ , rooted as  $s$ , which contains a shortest path from  $s$  to every vertex of  $G$ .
- ▶ Such a tree is called **shortest path spanning tree**.

## Weighted Graph and its Shortest Path Spanning Tree

A Weighted Graph  $G$

A Shortest Path  
Spanning Tree of  $G$

# Dijkstra's Algorithm

- In the algorithm, graph  $G(V, E, W)$  is represented by distance matrix  $D$ .

/\*  $s$  is the source vertex and  $S$  is the partial solution set such that the shortest paths from  $s$  to each vertex in  $S$  lies wholly in  $S$ . For each vertex  $v \in V - S$ ,  $d[v]$  contains the distance of current shortest path from  $s$  to  $v$  passing only through vertices of  $S$ .\*/

# Dijkstra's Algorithm(contd.)

```
 $S = \{s\}; \ d[s] = 0;$   
 $\text{for } (v \in V - S) \ d[v] = D[s, v];$   
 $\text{while } (S \neq V) \ \{$   
    Choose a vertex  $w$  in  $V - S$  such that  
         $d[w]$  is a minimum;  
    add  $w$  to  $S$ ;  
     $\text{for } (v \in V - S) \ d[v] = \min\{d[v], d[w] + D[w, v]\};$   
}
```

# Example

- Initially:  
 $S = \{v_0\}$ ,  $d[v_0] = 0$ ,  
 $d[v_i]$  is  $2, +\infty, +\infty, 10$ ,  
 $i = 1, 2, 3, 4$ ;
- At the first iteration:  
 $w = v_1$  is selected, since  
 $d[v_1] = 2$  is minimum;
- Then:  
 $d[v_2] = \min\{+\infty, 2 + 3\} = 5$   
 $d[v_4] = \min\{10, 2 + 7\} = 9$

# Transition of variables

Iter.	$S$	$w$	$d[w]$	$d[v_1]$	$d[v_2]$	$d[v_3]$	$d[v_4]$
Init.	$\{v_0\}$	—	—	2	$+\infty$	$+\infty$	10
1	$\{v_0, v_1\}$	$v_1$	2	2	5	$+\infty$	9
2	$\{v_0, v_1, v_2\}$	$v_2$	5	2	5	9	9
3	$\{v_0, v_1, v_2, v_3\}$	$v_3$	9	2	5	9	9
4	All	$v_4$	9	2	5	9	9

# Single-source shortest path of “Example”

# correctness of Dijkstra's algorithm

We now prove the correctness of Dijkstra's algorithm by induction on the size of  $S$ .

- Basis.  $|S| = 1$ . The shortest path from  $s$  to itself has length 0 and a path from  $s$  to  $v$ , wholly within  $S$  except for  $v$ , consists of the single edge  $(s, v)$ . Thus,  $d[v]$  was correctly computed.  
(for  $(v \in V - S)$   $d[v] = D[s, v]$ ;) )

## correctness of Dijkstra's algorithm(contd)

- ▶ Induction Hypothesis. Assume the following statements are true for  $|S| = k \geq 1$  :  $S$  is the partial solution set such that the shortest paths from  $s$  to each vertex in  $S$  lies wholly in  $S$ . For each vertex  $v \in V - S$ ,  $d[v]$  is the distance of current shortest path from  $s$  to  $v$  passing only through vertices of  $S$ .

# correctness of Dijkstra's algorithm(cntd2)

- Inductive Step. For  $|S| = k$ , assume  $w \in V - S$  such that  $d[w]$  is a minimum is chosen and added to  $S$  ( $|S|$  becomes  $k + 1$ ). If  $d[w]$  is not the distance of a shortest path from  $s$  to  $w$ , then there must be a shorter path  $P$  such that  $P$  contains some vertex other than  $w$  which is not in  $S$ . Let  $v$  be the first such vertex on  $P$ .

## correctness of Dijkstra's algorithm(cntd3)

- But then the distance from  $s$  to  $v$  is shorter than  $d[w]$ , and moreover, the shortest path from  $s$  to  $v$  lies wholly within  $S$ , except for  $v$  itself. Thus, by the inductive hypothesis,  $d[v] < d[w]$ , a **contradiction**.

# correctness of Dijkstra's algorithm(cntd4)

- We conclude that the path  $P$  does not exist and  $d[w]$  is the distance of the shortest path from  $s$  to  $w$  that lies wholly in  $S$ . From the update operation

$$d[v] = \min\{d[v], d[w] + D[w, v]\},$$

we know  $d[v]$  are correctly computed.

# An Efficient Implementation of Dijkstra's Algorithm

- ▶ If the graph is represented by an adjacent (distance) matrix, the time complexity of Dijkstra's algorithm is  $O(|V|^2)$ .
- ▶ Dijkstra's algorithm can be made more efficiently by maintaining the graph using **adjacency(distance) lists** and keeping a priority queue of the nodes not in  $S$ .  
Next slide shows the pseudo code of such an implementation.

# Dijkstra's Algorithm(List ver.)

/\*  $s$  is the source vertex and  $S$  is the partial solution set such that the shortest paths from  $s$  to each vertex in  $S$  lies wholly in  $S$ .

For each vertex  $v \in V - S$ ,  $d[v]$  contains the distance of current shortest path from  $s$  to  $v$  passing only through vertices of  $S$ .

Here  $D[i, j]$  describes distance list<sup>\*</sup>/

## Dijkstra's Algorithm(List ver.)2

```
 $S = \{s\}; d[s] = 0;$   
for  $(v \in V - S)$   $d[v] = D[s, v];$   
for  $(v \in V - S)$  construct  $d[v]$  into  
    a minimum heap;  
while  $(S \neq V)$  {  
    delete  $d[w]$  from the heap and add  $w$  to  $S$ ;  
    for  $(v \in V - S)$  if  $((w, v) \in E)$   
         $\{d[v] = \min\{d[v], d[w] + D[w, v]\};$   
        restore the heap condition;  
}
```

# An Efficient Implementation of Dijkstra's Algorithm

- Under this implementation, the time complexity of Dijkstra's algorithm is  $O((|V| + |E|) \log |V|)$ .

# Difference between Minimum Spanning Tree and Shortest Path Spanning Tree

- ▶ In Prim's algorithm, vertices and edges are added to a tree one by one, each step choosing the shortest possible edge from  $V$  to  $V - T$  to add.
- ▶ In Dijkstra's algorithm, the edge  $(u, v)$  to be added may not be the closest, but minimizing  $d(u) + D[u, v]$  within all paths from the source to  $v$ .

# Shortest Paths in the Graph with Unit Edge Length

- ▶ Given a graph  $G(V, E)$  whose distances of edges are 1, the shortest path from  $u$  to  $v$  is the path from  $u$  to  $v$  with the minimum length (the number of edges). Dijkstra's algorithm may be used to solve this problem.  
However, a simpler algorithm for this problem is BFS algorithm.

# All Pairs Shortest Path Problem

- ▶ Warshall's algorithm      Floyd's algorithm
